Abstract: Introduction: Maternal nutrition during pregnancy and/or lactation is a fundamental determinant of maternal and child health. So, it can halt the long-term and irreversible consequences of malnutrition. The burden of undernutrition among women and children became a significant public health problem in low and middle-income countries including Ethiopia. However, lactating mothers in these countries are one of the nutritionally vulnerable groups. There are limited studies conducted to assess the nutritional status of lactating women. So, the aim of this study was to assess the chronic energy deficiency and its associated factors among lactating mothers in Debre Tabor General Hospital, Northcentral Ethiopia. Methodology: An institutional based cross-sectional study was conducted to assess the nutritional status of 266 lactating mothers were selected by systematic random sampling from October 2017 to January 2018. The data were collected by face to face interview by using a pre-tested and structured questionnaire. The physical measurements were taken at the end of the interview. The bivariate and multivariable logistic regression were used to identify associated factors. The variables with a p-value <0.2 were used to select candidate variables for multivariable logistic regression. A p-value of ≤ 0.05 was used to declare statistical significance. Result: A total of 251 lactating mothers were included in the study which makes the response rate of 94.36%. The prevalence of chronic energy deficiency among lactating women was 17.9% (95% CI (13.5, 23.1)). Women's who had daily laborer husband (AOR: 5.02, 95%CI (1.36, 18.50)), had not Post Natal Care (PNC) follow up (AOR: 6.39 95% CI (1.69, 24.13)), and ate 2 times per day (AOR: 4.87, 95% CI (1.44, 16.51)) were the contributing factors for the development of chronic energy deficiency. Conclusion: In this study, CED is a medium public health problem. The husband's occupation, postnatal care follow up, and maternal feeding frequency were the contributing factors. Health professionals shall provide health education for pregnant and lactating women's behavior regarding nutrition and health to improve maternal nutrition.

Keywords: Chronic Energy Deficiency, Lactating Mothers, Prevalence, Ethiopia

1. Introduction

Maternal malnutrition is the problem of many developing countries which lead to acute and chronic diseases, poor healthy development, and loss of productivity at individual and community level at large. Maternal undernutrition includes both macro and micronutrient deficiencies [1]. In Ethiopia, undernutrition is a significant public health problem

among lactating and pregnant women till nowadays [2, 3].

To satisfy the nutritional requirement of lactating women, appropriate nourishment during pregnancy and lactation is very important for the adequate nutrient reserve to be used when it is inadequate. So, counseling on adequate nutrition during pregnancy is very important to prevent nutrients depletions during lactation [4]. Lactating mothers from low and middle-income countries are considered as a nutritionally

vulnerable group due to frequent pregnancy, inappropriate care, nurturing the family and workload which intern leads to maternal morbidity and mortality [5].

The development of chronic energy deficiency (CED) among lactating mother is common due to the higher requirement of nutrients [6]. The maternal nutrients depletion occurred due to inadequate intake of nutrients that intern leads to poor nutritional status, poor breast milk quality, and drop child growth and development [7, 8].

Dietary adequacy before, during, and after pregnancy will help to prevent CED throughout the life cycle [9, 10]. An acceptable dietary diversity score among lactating mother is important to tackle malnutrition [11].

The prevalence of CED among lactating mothers in different parts of Ethiopia ranges from 17.5% to 25.6% [12-16].

In Ethiopia, studies suggest that current age of the mother, age at first pregnancy, frequency of ANC visit, delivery area, absence of nutritional information and education in the community, Vitamin A supplementation during postpartum period, consumption of iodized salt and extra meal during lactation, length of breastfeeding, meal frequency, maternal and father educational and occupational status and family size were the major determinant factors for the development of CED among lactating mothers [13-17].

Even if the causes of malnutrition are well-established facts, the magnitude and associated factors differ from area to area. Still Studying the magnitude and associated factors of CED among Lactating mothers is very important to prioritize, design and initiates intervention programs based on the relevant information. So, conducting this study was very important to determine the magnitude and its associated factors of CED among lactating mothers.

2. Methods and Materials

2.1. Study Area

The study was conducted in Debre Tabor General Hospital, Debre Tabor Town. Debre Tabor is the capital Town of South Gondar Zone which is located 666Kms Northcentral of Addis Ababa, the capital city of Ethiopia. The hospital is providing services for around 2,047,206 peoples (male = 1,038,913 and female = 1,008,293) according to 2007 census. Debre Tabor General Hospital offers health services which include inpatient, outpatient, neonatal intensive care, TB/ leprosy, antenatal care, delivery, postnatal care, and family planning services to the urban as well as the rural communities of South Gondar Zone. The Hospital gives services for 139,787 people and more than one third were adult women in 2016/17 according to the hospital annual report. Currently, this is the only General Hospital in the zone to deliver the basic services for the clients form 15 administrative districts.

2.2. Study Design and Period

An institution-based cross-sectional study was conducted

from October 2017 to January 2018.

2.3. Study Population

All lactating women were included in the study but those who were critically ill during data collection time, pregnant, and with a difficulty to take physical measurements were excluded.

2.4. Sample Size Determination and Sampling Procedure

The sample size was determined by using single population proportion formula with the assumption of 19.5% proportion of CED/underweight among lactating mother from the most recent study in Adama, Eastern Ethiopia [13], 95% of confidence level, and 5% of marginal error. Then, the final sample size became 266 after adding 10% of the non-response rate.

The study participants were selected by using a systematic random sampling technique. First, we estimated the number of lactating women at the site of post-natal care, immunization, family planning, growth monitoring, and pediatrics clinic service users for 4 consecutive months. The expected number of lactating mothers who came for these services was 2011. Then, we calculated the K^{th} interval and that was 8. Then the information was collected at the 8th interval in each health service/care units.

2.5. Operational Definition

Chronic Energy Deficiency of a lactating mother: currently breastfeeding mothers for her infant or child had a BMI of $<18.5 \text{ kg/m}^2$ [17].

Minimum Women Dietary Diversity Score (MWDDS): when a lactating mother consumed more than or equal to 5 food group among 10 food groups within 24hours [17, 18].

2.6. Data Collection Methods

The interview administered structured questionnaire was used to assess CED and its associated factors. The questionnaire was first prepared in the English and then translated into Amharic, the local language of the study area by linguistic professionals and it was translated back to English by another linguistic professional to check its consistency. Two-days training with pretest for 5 diploma midwives was given on the objective, the relevance of the study, confidentiality of information, respondent's right, informed consent and techniques of the face to face interview and physical measurements of height and weight. The supervisor was following the data collection process throughout the data collection period along with the principal investigator. The measurement of the weight of the lactating mothers was done by using calibrated portable electronic digital scale (Seca, Germany model) and recorded to the nearest 0.1kg. The height was measured by using a portable height-measuring board with a sliding head bar and recorded the nearest 0.1cm. These measures of height and weight were done three times without shoes and with a possible light closing. The measure of height and weight was recorded on

the questionnaire and was later used to calculate the body mass index (BMI).

2.7. Data Quality Assurance

The pre-test was done outside of the study area (Nefas Mewucha Primary Hospital) on 20 samples before the actual data collection period and necessary corrections were made on the questionnaire. The weight scale has been calibrated by using 1kg standard weight, height measurements were checked with other meter taps. During the data collection time, communication between the data collectors, supervisors and the principal investigator was held on a daily basis to update data collection progress and address problems faced. A definition of concepts and terms had been done clearly with the Amharic language to avoid ambiguity. The supervisors and data collectors were recruited outside the hospital to avoid information bias due to familiarization. The collected data were checked for completeness and consistency by the supervisors and the principal investigator during and after data collection.

2.8. Study Variables

The dependent variable was chronic energy deficiency among lactating mothers and the independent variables were socio-demographic factors (address, age, educational status, Marital status, ethnicity, religion, husband educational status, monthly family income), obstetric related variables (age at first pregnancy (in years), number of pregnancy, age at first pregnancy, number of live birth), current admission to therapeutic feeding unit, dietary diversity score, the frequency of maternal feeding, health-related variables (existence of chronic illness and diarrhea) variables, and physical measurements.

2.9. Data Analysis

The data were edited, coded and entered to Epidata version 3.1 and exported to SPSS version 21 for cleaning and analysis. The data were analyzed for descriptive, bivariate, and multivariable analysis. The principal component analysis was done to build a wealth index. During binary logistic regression, a variable with a p-value <0.2 used to select

candidate variables for multivariable logistic regression. In this study, a p-value of $\leq 5\%$ was considered as statistically significant after fitting into multivariable logistic regression. For calculated odd ratios, 95% of confidence intervals had been used to saw the degree of association. The Hosmer-Lemeshow goodness of fit test was performed on the logistic model for CED of lactating mothers (P-value = 0.652%).

2.10. Ethical Consideration

Ethical clearance and permission were obtained from the Institutional Review Committee of Debre Tabor University and then the written permission was obtained from Debre Tabor General Hospital administrative office. Informed consent was obtained from the study participants. The purpose of the study was explained to them. Lastly; before starting the interview and taking a measurement, we informed each participant that they had the right to withdraw from the study at any time. They were assured Confidentiality was maintained at all levels of the study and was assured about the presentation of the final result at scientific community workshops and publication in a reputable journal without a personal identifier. Mothers with chronic energy deficiency were referred to the respective unit of the hospital by using internal referral slip of the Hospital. Finally, all mothers with chronic energy deficiency and overweight got nutritional education and counseling during data collection time.

3. Result

3.1. Socio-Demographic Characteristics

A total of 251 lactating mothers were included in the study with the response rate of 94.36%. The mean age \pm SD of the respondent was 29.69 ± 6.10 years. From 251, 233 (92.80%) were Amhara by ethnicity and the rest of them were Oromo (18 (7.20%)). Majority of the study participants 241 (96.0%) were married and the rest 10 (4%) were divorced. In terms of residency, near to three fourth (185 (73.7%)) were from the urban area. Near to one-third of the respondents were found between the age of 25 and 29yrs as shown in the table below (Table 1).

Table 1. Socio-demographic and economic characteristics of lactating mothers in Debre Tabor General Hospital January 2018 (n=251).

Variable	Categories	Frequency	%
Current Age	20 – 24	51	20.3
	25 – 29	86	34.3
	30 – 34	53	21.1
	35 – 39	40	15.9
	40 – 44	21	8.4
Religion	Orthodox	214	85.3
	Muslim	30	12.0
	Protestants	7	2.8
Respondent's educational status	unable to read and write	46	18.3
	able to read and write	46	18.3
	primary education	26	10.4
	secondary education	47	18.7
Husband's educational status	tertiary education and above	86	34.3
	unable to read and write	25	10.0
	able to read and write	45	17.9

Variable	Categories	Frequency	%
	primary education	23	9.2
	secondary education	46	18.3
	tertiary education and above	112	44.6
Respondent's occupation	Merchant	59	23.5
	Government employer	81	32.3
	Housewife	111	44.2
Husband's occupation	Merchant	72	28.7
	Government employer	111	44.2
	Daily labor	22	8.8
Wealth index	Farmer	46	18.3
	Very poor	32	12.7
	Poor	43	17.1
	medium	87	34.7
	Rich	52	20.7
	Wealthiest	37	14.7

3.2. Obstetrics Related Characteristics

The mean age \pm SD of lactating mothers at first pregnancy was 21.90 ± 4.23 years and the minimum age was 15 years. The mean age of the index child and number of average pregnancy with standard deviation were 11.02 ± 8.59 months and 2.30 ± 1.43 respectively. More than fifty percent of respondents were multi-para and more than 90% were attending antenatal care for the index child as shown in (Table 2).

Table 2. Obstetrics related characteristics of lactating mothers in Debre Tabor General Hospital, January 2018 ($n = 251$).

Variable	Categories	Frequency	%
Age at first pregnancy	15 - 19	84	33.5
	20 - 24	94	37.5
	25 - 29	73	29.1
Gravidity	Primi gravida	91	36.3
	Multigravida	147	58.6
	Grand gravida	13	5.2
Number of live birth	≤ 4	238	94.8
	> 4	13	5.2
Current FP utilization	Yes	160	63.7
	No	91	36.3
Attending ANC for current child	Yes	236	94.0
	No	15	6.0
Place of delivery	Health center	86	34.3
	Home	25	10.0
	Hospital	140	55.8
Attending PNC for current child	Yes	224	89.2
	No	27	10.8
Age of current breastfeeding child in months	< 6	66	26.3
	6 - 11	74	29.5
	12 - 23	111	44.2

3.3. Health-Related Factors

All most all the respondents had no diarrhea 236 (96.3%) in the last two weeks and none of the respondents reported any known chronic or acute diseases. None of them were admitted for targeted supplementary feeding or food by prescription programs and have no edema.

3.4. Dietary Related Characteristics

The average dietary diversity score (DDS) of lactating mother's \pm SD was 4.96 ± 0.75 . By using 24-hour dietary recall and 10 food groups, all most all of the lactating mothers had good dietary diversity 246 (98%). In terms of

meal frequency, lactating mothers who ate more than three times were 105 (41.8%), three times were 106 (42.2%), and two times were 40 (15.9%).

3.5. The Magnitude of Chronic Energy Deficiency

The mean \pm SD of weight and height of respondent was 51.30 ± 6.43 Kg and 1.57 ± 0.05 m respectively. The mean \pm SD of BMI was 20.73 ± 2.35 Kg/m². The minimum BMI was 16.0 Kg/m² and the maximum was 32.7 kg/m². The overall chronic energy deficiency/underweight was 45 (17.9%, 95% CI (13.5, 23.1)). The magnitude of overweight and normal weight were 15 (6.0%) and 191 (76.1%) respectively.

3.6. Associated Factors of Chronic Energy Deficiency

In bivariate logistic regression; residency, current age, respondent educational status, husband occupation, current family planning usage status, age at 1st pregnancy, gravidity, ANC follow-up during the pregnancy of index child, PNC follow-up during the pregnancy of index child, current frequency of maternal feeding, number of live-birth and wealth index were significant variables. In multivariable logistic regression analysis; having PNC follow up during index child, maternal current feeding frequency, and husband occupation were the associated factors for the development of chronic energy deficiency among lactating women as

shown in the table below (Table 3). Duration of breastfeeding or the age of the child was not significantly associated with CED in this study even if it leads to a higher amount of caloric intake.

Women's who had daily laborer husband were 5 times (AOR: 5.02, 95%CI (1.36, 18.50)) more likely to develop CED as compared to merchant husband. Lactating mothers who had no PNC follow up were 6 times (AOR: 6.39, 95% CI (1.69, 24.13)) more likely to acquire CED. Lactating women who ate only 2 times per day were 5 times (AOR: 4.87, 95% CI (1.44, 16.51)) more likely to had CED as compared to those who ate more than three times per day.

Table 3. Factors associated with chronic energy deficiency among lactating mothers in Debre Tabor General Hospital, January 2018 (n =251).

Variable	CED		COR (95% CI)	AOR (95% CI)	
	Yes	No			
Residency	Urban	26	159	1	1
	Rural	19	47	2.47 (1.26, 4.85)	0.19 (0.03, 1.25)
	20-24	5	46	0.27 (0.07, 1.01)	2.32 (0.21, 25.55)
Current age	25-29	13	73	0.44 (0.15, 1.35)	3.73 (0.54, 25.84)
	30-34	8	45	0.44 (0.13, 1.48)	2.23 (0.33, 15.19)
	35-39	13	27	1.20 (0.38, 3.82)	1.91 (0.31, 8.98)

4. Discussion

Different kinds of literature show that undernutrition among reproductive age group women decreased worldwide but it is a major public health problem in Africa and Asai including Ethiopia [19]. The household economic status an important determinant factor to have access to food which is

unlikely among women [20, 21] which may worsen the situation of undernutrition.

In this study, the prevalence of CED was 17.9%, 95% CI (13.5, 23.1) similar with the study conducted at Wombera woreda and Adama [12, 13] and lower than a study conducted in Dedo and Seqa Chekorsa Districts, Jimma Zone, Ethiopia (40.6%) [22] and Vietnam [23]. The probable

reason may be the different socioeconomic status and the dietary habit of the respondents.

Lactating mothers who had daily laborer husband were 5 times (AOR: 5.02, 95% CI (1.36, 18.50)) more likely to develop CED as compared to those who had government employee husband which is similar with a study done in the lowland area of Alamata Ethiopia [16] and India [24, 25]. The reason could be mothers who had daily laborer husband would have low economic status and tasks which may demand extra calories [15, 26].

Lactating Mothers who had no PNC follow up were 6 times (AOR: 6.39, 95% CI (1.69, 24.13)) more likely to had CED which is similar with the study conducted at Samre Woreda, Ethiopia [14]. The possible justification may be having PNC follow up will increase the access for nutrition-related knowledge and in turn, it may affect the choice and amount of dietary intake and this [27].

Lactating women who ate at only 2 times per day were 5 times (AOR: 4.87, 95% CI (1.44, 16.51)) more likely to experience CED as compared to those who ate more than three times per day which is similar with a study done in the Alamata and Samre Woreda, Ethiopia [14, 16]. The probable reason might be taking extra meal will increase the amount of energy that can be demanded by lactation [28].

In this study sociodemographic variables like age, wealth status, respondent's occupation, and education were not significant. But in the other studies, these variables were significant and associated with the development of undernutrition among women [29]. Also, other factors related to obstetrics and diet were not significant but these variables were significant in other studies [30]. This variation might be due to the multifactorial cause of undernutrition in developing and developing countries [1, 19, 31].

5. Conclusion

The prevalence of chronic energy deficiency among lactating women was a medium public health problem. The factors associated with CED were the husband's occupation, postnatal care follow up, and the frequency of maternal feeding. Health professionals shall provide health education for pregnant and lactating women's behavior regarding nutrition and health care follow up to improve maternal nutrition.
